

Creating the Footer and get_footer

`get_footer()` is as you guessed it the footer of a template. It works very similar to the `get_header()` and `get_sidebar()` function in where WordPress will look for a file called `footer.php`.

Again if the template needs a separate footer than the main preloaded WordPress one then you would create `footer-blog.php` file. Then inside of your template theme you would have something like this to call that file.

```
<?php get_footer('blog'); ?>
```

That function alone is enough to call the correct file and load it as the sidebar in our template.

Another example

As in the documentation for footer you could have logic around the calls for the footer. This would alter which footer gets loaded depending on the type of page that you are currently on.

```
<?php
if ( is_home() ) :
    get_footer( 'home' );
elseif ( is_404() ) :
    get_footer( '404' );
else :
    get_footer();
endif;
?>
```
